

Same predictions. Different patients. Different scores.

A controlled test of performance attribution in ARC aphasia prediction

(a) The attribution problem

Our control: freeze predictions, switch the scoring patients

* Secondary published-list analysis. RF scores are mean Pearson r across 20 repeats.

(b) Score shifts with fixed individual predictions

- 1 Cohort variation is larger**
Than model variation in the tested competitive set
- 2 Scores shift without refitting**
Fixed predictions produce both score gains and losses
- 3 Composition helps explain**
The main FLAIR and task-fMRI score losses

(c) The argument across the study

A higher score alone does not identify a method gain.
